If curl is hanging your request, you need to either close the connection or supply a content-length header field (set to zero). See RFC 7230, Section 3.3.3. (source: <https://stackoverflow.com/a/52869383>).

For those seeing strange results when using a server testing tool like `oha` - make sure you implement keep-alive. It is the default in HTTP/1.1, and if not implemented, you'll probably close the connection while the server testing tool still means to use it for the next request. This won't present itself as a problem when testing with `curl`, because that's a one-connection-one-request scenario.
