

- A full list of API keys can be found in [the docs](#).
- `request_api_version` : The version of the API to use for the request.
  - For example, the `APIVersions` request supports multiple versions: 0, 1, 2, 3 and 4.
- `correlation_id` : A unique identifier for the request.
  - This value is echo-ed back in the response.
  - (This is the value you hardcoded in the previous stage!)
- `client_id` : A string identifying the client that sent the request.
- `tagged_fields` : Optional tagged fields
  - This can be ignored for now, they're [optional tagged fields](#) used to introduce additional features over time.
  - The value for this will always be a null byte in this challenge (i.e. no tagged fields are present)

In this stage, you'll only need to parse the `correlation_id` field from the request. You can ignore the other fields for now.

## Tests

The tester will execute your program like this:
