Wondering why "P" stands for in "PX"?

Antirez (Redis's author) answered this [here](#):

P stands for precision, since the precision is improved by using milliseconds.

Redis started out by only offering second-level precision for key expiry. Millisecond-level precision was introduced later.

It is worth noting the named argument "px" is passed using lowercase chars, like the command name.

Also, worth noting that its value is passed as a string rather than an integer.

Also worth noting that the value for PX is sent encoded as a STRING. So if you, like me had assumed your parser would parse it into an Integer or a double it wont.... If anyone knows why its sent as a bulk string I would love to know seems weird.
