HARD

In this stage, you'll add support for executing a transaction that contains multiple commands.

Executing a transaction

When the [EXEC](#) command is sent within a transaction, all commands queued in that transaction are executed.

The response to [EXEC](#) is an array of the responses of the queued commands.

Example:

```
$ redis-cli
> MULTI
OK
> SET foo 41
QUEUED
> INCR foo
QUEUED
> EXEC
1) OK
2) (integer) 42
```

In the above example, `OK` is the response of the `SET` command, and `42` is the response of the `INCR` command.
