Instructions   </> Code Examples   ▶ Screencasts   🎓 Concepts   💬 Forum   **Stage #AP6**   (Pending)

Your Task   (Pending)   Share Feedback   MEDIUM

In this stage, you'll implement the `/files/{filename}` endpoint, which returns a requested file to the client.

Tests

The tester will execute your program with a `--directory` flag. The `--directory` flag specifies the directory where the files are stored, as an absolute path.

```
$ ./your_program.sh --directory /tmp/
```
The tester will then send two `GET` requests to the `/files/{filename}` endpoint on your server.

First request

The first request will ask for a file that exists in the files directory:

```
$ echo -n 'Hello, World!' > /tmp/foo
$ curl -i http://localhost:4221/files/foo
```
