Your program should respond with a **Bulk string** where each line is a key value pair separated by `:` . The tester will only look for the `role` key, and assert that the value is `master` .

Notes

- In the response for the `INFO` command, you only need to support the `role` key for this stage. We'll add support for the other keys in later stages.

- The `# Replication` heading in the response is optional, you can ignore it.

- The response to `INFO` needs to be encoded as a **Bulk string**.

  - An example valid response would be `$11\r\nrole:master\r\n` (the string `role:master` encoded as a **Bulk string**)

- The `INFO` command can be used without any arguments, in which case it returns all sections available. In this stage, we'll always send `replication` as an argument to the `INFO` command, so you only need to support the `replication` section.
