Another gotcha: many HTTP libraries will encode query parameters "for you", even if you already give a URL encoded string. Be sure you're not sending a double-encoded query parameter!

If you are struggling to decode the bencoded peers response with the same logic that you used on the sample torrent file, be certain that your web request logic isn't converting it to a string and then back into a byte array somehow. Certain languages' web request libraries have different methods for using a request as bytes vs as text.

(C++) I bumped into an interesting problem. I got [**301 Moved Permanently**](#) response from the server on the first test. To solve this one, I set CURLOPT_FOLLOWLOCATION option with `curl_easy_setopt` function before doing `curl_easy_perform`. Maybe it will help someone.
